1           This application claims the benefit of U.S. Provisional Application No.  
2   60/463,882 filed April 17, 2003.

### 3                                   FIELD OF THE INVENTION

4           The present invention relates to a structural connector particularly useful in the oil  
5   and gas industry. In particular, the invention relates to a structural connector that allows  
6   for connection of elements of a drilling rig substructure in significantly less time and with  
7   less risk to rig personnel than previous pin-type connectors.

### 8                                   BACKGROUND OF THE INVENTION

9           In most land-based drilling operations, such as when drilling for oil and gas on  
10   land, it is necessary to transport a drilling rig to the site where the drilling operations will  
11   take place. Typically, these drilling rigs are very large and, thus, must be transported to  
12   the drilling site in several pieces. These rigs are transported in pieces that comprise the  
13   three main sections of a drilling rig: the substructure, the equipment floor, and the mast.  
14   Depending on the size of the drilling rig, the substructure, the equipment floor, and the  
15   mast may each be further broken down into multiple pieces for ease of transportation.

16           The equipment floor of the drilling rig is comprised of several segments, all of  
17   which, when assembled together, provide the platform or the "floor" for the drilling  
18   equipment and the mast that will be used in the drilling operations. The equipment floor  
19   may be constructed in a variety of ways, but is typically formed by using I-beams or box  
20   girders for the sides and interconnecting the sides with spreaders or other cross members.  
21   The equipment floor can, however, be constructed in any desired manner to achieve the  
22

1 necessary structural integrity and to provide the necessary support for the equipment  
2 used.

3 It has become the custom to use an equipment floor that is elevated above ground  
4 level in order to provide clearance for relatively tall blow-out prevention apparatus and  
5 other wellhead equipment used in drilling oil and gas wells. One embodiment of such an  
6 elevated-floor drilling rig structure is disclosed in United States Patent No. 4,831,795 to  
7 Sorokan.

8 If an elevated equipment floor is used, the equipment floor is often connected to a  
9 collapsible elevating frame that, when assembled, can be raised – thereby raising the  
10 equipment floor above the ground. The collapsible elevating frame is part of the  
11 substructure and, like the equipment floor, this collapsible elevating frame is comprised  
12 of several pieces that must be transported to the drilling site.

13 Once the pieces of the drilling rig reach the site, the complete drilling rig must be  
14 reassembled so that drilling operations can commence. Assembling the drilling rig  
15 components on site, however, has proven to be a relatively complex and time consuming  
16 process. In many of the prior art drilling rig structures, the equipment floor and the  
17 substructure must be constructed and connected together in, essentially, a piece-by-piece  
18 operation.

19 Further, after assembling the various pieces of the equipment floor and the  
20 substructure, prior art drilling rig structures require drilling operators to “pin” the  
21 equipment floor and the substructure together using large pins that are capable of  
22 handling the significant forces and stresses that are imposed on the pinned connections.  
23 The process of pinning the equipment floor to the substructure requires the rig personnel

1 to align pin holes in the sides of the equipment floor with pin holes in the sides of the  
2 substructure. Once the pin holes are aligned, it is necessary for one person to hold the pin  
3 in place while another person drives the pin through the pin holes with a sledge hammer  
4 or other device, thereby forming a connection between the equipment floor and the  
5 substructure. This process is repeated until all the pins connecting the equipment floor  
6 and the substructure are driven in place. Given the fact that the equipment floor and the  
7 substructure typically require in excess of twenty (20) pins to connect them together, the  
8 process of pinning these components together takes a significant amount of time.  
9 Ultimately, the significant amount of time required to assemble the drilling rig  
10 components increases the expense of using such a rig.

11 Moreover, the process of pinning these components together can be dangerous for  
12 the rig personnel performing such task. Specifically, the task of holding the pin  
13 connectors in place as they are driven through the pin holes with a sledge hammer or  
14 other device poses a significant risk of injury to the rig personnel performing such task.

15 Accordingly, what is needed is a structural connector capable of handling the  
16 significant forces and stresses required to hold the elements of the drilling rig together  
17 while at the same time allowing for easier connection and shorter assembly time. It is an  
18 object of the present invention to provide an apparatus and method for creating a  
19 structural connector capable of handling significant forces and stresses while providing  
20 for easy and efficient connection of structural components. Those and other objectives  
21 will become apparent to those of skill in the art from a review of the specification below.

22

## SUMMARY OF THE INVENTION

A method and apparatus for providing a structural connection between components of a drilling rig is disclosed. The disclosed invention is a unique structural connector in which a section of the equipment floor of a drilling rig can be connected to the side boxes of the drilling rig substructure without the use of pins or other prior art connectors. The structural connector of the present invention utilizes specially-shaped fixed support members connected to, and extending through, support plates attached to the side boxes of the substructure to mate with specially-shaped mating lugs that are mounted on mating lug plates attached to the equipment floor of the drilling rig. The fixed support members are designed with contoured tops and substantially vertical walls that mate with similarly shaped notches in the mating lugs attached to the mating lug plates.

When the equipment floor is lowered into place between the side boxes of the substructure, the specially-shaped mating lugs engage the specially-shaped fixed support members and form a structural connection between the equipment floor and the side boxes of the substructure. The result is a high strength structural connector that allows for easier and more efficient connection of structural components.

## BRIEF DESCRIPTION OF THE DRAWINGS

The following figures form part of the present specification and are included to further demonstrate certain aspects of the present invention. The invention may be better understood by reference to one or more of these figures in combination with the detailed description of specific embodiments presented herein.

1           Figure 1 is a top view of the substructure of a typical elevated floor drilling rig  
2 showing the various components of the substructure.

3           Figure 2 is a side elevation view of a unitized equipment floor of a typical  
4 elevated drilling rig structure showing the various structural components of the  
5 equipment floor.

6           Figure 2a is a front elevation view of the unitized equipment floor shown in  
7 Figure 2 in the direction of line A-A.

8           Figure 3 is a side view of the mating lugs assembly with saddle-shaped mating  
9 lugs attached thereto according to one embodiment of the present invention.

10          Figure 3a is a top view of the mating lugs assembly shown in Figure 3.

11          Figure 3b is a detailed view of the saddle-shaped mating lugs shown in Figures 3  
12 and 3a.

13          Figure 4 is a side view of the support plate with fixed support members extending  
14 through the plate according to one embodiment of the present invention.

15          Figure 4a is a top view of the support plate shown in Figure 4 showing the fixed  
16 support members extending out from both sides of the plate according to one  
17 embodiment of the present invention.

18          Figure 4b is a detailed view of the fixed support members shown in Figures 4 and  
19 4a.

20          Figure 5 is a side view showing the support plate of Figure 4 aligned to receive  
21 the mating lugs assembly of Figure 3 to form a structural connector according to one  
22 embodiment of the present invention.

1           Figure 5a is a side view of the mating lugs assembly of Figure 3 connected with  
2           the support plate of Figure 4 to form a structural connector according to one embodiment  
3           of the present invention.

#### 4 5                           **DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS**

6           The following examples are included to demonstrate preferred embodiments of  
7           the invention. It should be appreciated by those of skill in the art that the techniques  
8           disclosed in the examples which follow represent techniques discovered by the inventor  
9           to function well in the practice of the invention, and thus can be considered to constitute  
10          preferred modes for its practice. However, those of skill in the art should, in light of the  
11          present disclosure, appreciate that many changes can be made in the specific  
12          embodiments which are disclosed and still obtain a like or similar result without  
13          departing from the spirit and scope of the invention. Moreover, although the present  
14          invention is discussed in the following paragraphs by reference to connecting a section of  
15          an equipment floor of a drilling rig to the side boxes of the rig, it will be apparent from  
16          the present disclosure that the structural connector of the present invention can be utilized  
17          to connect various structural members together and should not be limited to connecting  
18          together components of a drilling rig.

19          Referring to Figure 1, various components of the substructure 5 of a typical  
20          elevated-floor drilling rig are shown. The substructure shown in Figure 1 consists of  
21          three main components: side box 10, unitized equipment floor 20, and side box 11. The  
22          unitized equipment floor 20 is referred to as “unitized” in that the various spreader  
23          assemblies that comprise the structural components of this section of the drill floor are

1 connected together to form a one piece – or “unitized” – section of drill floor. These  
2 structural components consist of a setback spreader assembly 22, a drawworks spreader  
3 assembly 24, a rear spreader assembly 26, rotary beams 28, and tie beam spreaders 30.

4 In utilizing a unitized equipment floor 20, it is not necessary to perform the extra  
5 steps of connecting together each individual component of the equipment floor at the well  
6 site. The elimination of these steps results in a significant reduction in time spent  
7 assembling the drilling rig at the well site. The present invention is not, however, limited  
8 to use with only a unitized equipment floor. One of skill in the art will recognize that  
9 time savings are still achieved even if the structural connector of the present invention is  
10 attached to a portion of an equipment floor that is not unitized.

11 Figure 2 shows a side elevation view of the unitized equipment floor 20 shown in  
12 Figure 1. Figure 2 shows the components of the unitized equipment floor 20 connected  
13 together to form the structural support “frame” for the center portion of the rig floor of a  
14 typical drilling rig. In prior art drilling rigs, the unitized equipment floor 20, or, if no  
15 unitized assembly is used, the individual structural components of the spreader  
16 assemblies, must be “pinned” to the side boxes 10 and 11 in multiple locations. As  
17 shown in Figure 2, six pin connection points – designated 35a through 35f – are utilized  
18 along each side of the unitized equipment floor 20. As such, for the unitized equipment  
19 floor 20 shown in Figure 2, a total of twelve pin connection points are utilized to connect  
20 the unitized equipment floor 20 to the side boxes 10 and 11 of the substructure 5. One of  
21 skill in the art will recognize that depending on the size and weight of the unitized  
22 equipment floor 20, the number of pin connection points may be greater than or less than  
23 the twelve connection points shown in Figure 2.

1           In addition, the significant forces and stresses imposed on the pins connecting the  
2   unitized equipment floor 20 to the side boxes 10 and 11 of the substructure 5 typically  
3   require the use of two pins at each of the twelve pin connection points shown in Figure 2  
4   – for a total of twenty-four pins. As noted above, the number of pin connection points  
5   may vary according to the size and weight of the unitized equipment floor 20 and, thus,  
6   the number of pins may vary accordingly. With larger rigs, the number of pin connection  
7   points and pins used to connect the unitized equipment floor 20 to the side boxes 10 and  
8   11 of the substructure 5 can be substantial. As the number of pins increases, the amount  
9   of time required to assemble the drilling rig at the drill site increases. The structural  
10   connector of the present invention eliminates the pin-type connections of prior art drilling  
11   rigs and, thus, substantially reduces the amount of time required to assemble a drilling rig  
12   at the drill site.

13           Figure 2a shows a front elevation view of the unitized equipment floor 20 shown  
14   in Figure 2. As can be seen in Figure 2a, mating lugs assemblies 41 have been connected  
15   to the setback spreader assembly 22 of the unitized equipment floor 20 (such connection  
16   point corresponding to connection point 35f shown in Figure 2). The mating lugs  
17   assemblies 41 can be connected to the setback spreader assembly 22 through any suitable  
18   metal-to-metal connection method capable of handling the significant forces and stresses  
19   imposed on the mating lugs assemblies 40 and 41. In the preferred embodiment of the  
20   present invention, the mating lugs assemblies 41 are welded to the setback spreader  
21   assembly 22. In a similar fashion, additional mating lugs assemblies 41 can be attached  
22   to the unitized equipment floor 20 at each of the connection points designated 35a  
23   through 35e in Figure 2.

Figure 3 is an enlarged side view of the mating lugs assembly 41 shown in Figure 2a. In the preferred embodiment, the mating lugs assembly 41 is attached to the setback spreader assembly 22 along the entire length of the connection points a and b shown in Figure 3. In the preferred embodiment of the present invention, the mating lugs assembly 41 is welded in place at connection points a and b.

Figure 3 shows mating lug 46 and mating lug 47 attached to mating lugs assembly 41, as discussed in more detail below with reference to Figures 3a and 3b. Figure 3 also shows the unique “saddle” shape of mating lug 46 and mating lug 47. The shape of mating lugs 46 and 47 is shown in more detail in Figure 3b, discussed below.

Figure 3a is a top view of the mating lugs assembly 41 attached to the setback spreader assembly 22 as shown in Figure 3. As can be seen in Figure 3a, mating lugs assembly 41 preferably consists of two metal “plates,” mating lug plate 43 and mating lug plate 44, separated by a short distance. Mating lug plate 43 and mating lug plate 44 each have two mating lugs, mating lug 46 and mating lug 47, attached to their inside plate surface. Thus, the structural connector of one embodiment of the present invention utilizes four mating lugs at each mating lugs assembly. In the preferred embodiment of the present invention, mating lugs 46 and 47 are welded to the inside surfaces of mating lug plates 43 and 44. One of skill in the art will recognize that mating lugs 46 and 47 can be attached to mating lug plates 43 and 44 by any suitable metal-to-metal connection method that is capable of handling the significant forces and stresses imposed on the mating plates and mating lugs.

Further, in an alternative embodiment of the present invention, the unique shape of the support notch of the mating lugs 46 and 47 may be cut into mating lug plates 43

1 and 44 in lieu of attaching mating lugs 46 and 47 to the surfaces of mating lug plates 43  
2 and 44. Cutting the unique shape of the support notch of the mating lugs 46 and 47 into  
3 mating lug plates 43 and 44 can be used for smaller drilling rigs with lighter equipment  
4 floors, as cutting material out of mating lug plates 43 and 44 may reduce the load  
5 handling capability of the plates.

6 Mating lug 46 and mating lug 47 are specially shaped to achieve the objectives of  
7 the present invention. As shown in detail in Figure 3b, mating lugs 46 and 47 each  
8 consist of a square or rectangular metal piece 50 with a uniquely shaped support notch  
9 51. Support notch 51 is specially shaped to have vertical, or substantially vertical, side  
10 walls 52 and 53 and a contoured top surface 54. Additionally, support notch 51 is shaped  
11 with tapered guide surfaces 55 and 56 at the entry point of the support notch 51. As  
12 discussed with reference to Figures 4 – 4b, the unique shape of support notch 51 is  
13 specially designed to mate with the uniquely shaped fixed support members in  
14 accordance with the present invention.

15 Mating lug plates 43 and 44 are specifically shaped such that mating lugs 46 and  
16 47 can be attached to the plates at locations that allow for unhindered access to the  
17 support notch 51 of both mating lugs 46 and 47. Specifically, as shown in Figure 3,  
18 mating lug 47 is attached to mating lug plate 44 at a location that is lower than the  
19 attachment point for mating lug 46 and closer to setback spreader assembly 22.  
20 Conversely, mating lug 46 is attached to mating lug plate 44 at a higher location than the  
21 attachment point for mating lug 47 and further from setback spreader assembly 22.  
22 Similarly, as shown in Figure 3a, a second set of mating lugs 46 and 47 is attached to  
23 mating lug plate 43 at the same locations. As discussed in reference to Figures 5 and 5a

1 below, this configuration allows mating lugs 46 and 47 on mating lug plates 43 and 44 to  
2 mate with the fixed support members of the support plate attached to the side boxes of the  
3 substructure to form the structural connector of the present invention.

4 Referring now to Figure 4, the support plate 60 of a preferred embodiment of the  
5 present invention is shown. As can be seen in Figure 4, support plate 60 is attached to  
6 side box 11 of the drilling rig substructure 5 (as designated in Figure 1). Support plate 60  
7 is attached to side box 11 at a location aligned with connection point 35f such that it can  
8 mate with the corresponding mating lugs assembly 41 attached to the unitized equipment  
9 floor 20 at connection point 35f. Support plate 60 can be connected to the side box 11 of  
10 the substructure through any suitable metal-to-metal connection method capable of  
11 handling the significant forces and stresses imposed on the support plate 60. In the  
12 preferred embodiment of the present invention, the support plate 60 is welded to the side  
13 box 11. In a similar fashion, additional support plates 60 can be attached to side box 11  
14 at locations that are aligned with each of the connection points designated 35a through  
15 35e in Figure 2 such that the support plates 60 can mate with the mating lugs assemblies  
16 41.

17 In accordance with the preferred embodiment of the present invention, fixed  
18 support member 61 and fixed support member 62 are attached to and extend outwardly  
19 from both sides of support plate 60. Figure 4a is a top view of the support plate 60  
20 connected to side box 11. Figure 4a shows fixed support members 61 and 62 extending  
21 outwardly from both sides of the support plate 60. In the preferred embodiment of the  
22 present invention, fixed support members 61 and 62 extend outwardly from the sides of  
23 support plate 60 approximately 1-2 inches. The above range of distance is given by way

1 of example only. One of skill in the art will recognize that the distance fixed support  
2 members 61 and 62 extend out from the sides of support plate 60 can vary significantly  
3 depending on several factors, including, but not limited to, the loads imposed on the  
4 support plate and fixed support members, the size of the fixed support members  
5 themselves, the size of the support plate, and the materials used to make the support  
6 members and the support plate.

7 The fixed support members 61 and 62 are shown in more detail in Figure 4b. As  
8 can be seen in Figure 4b, the fixed support members 61 and 62 are specially shaped to  
9 have vertical, or substantially vertical, side walls 66 and 67 and a contoured top surface  
10 68. The shape and size of fixed support members 61 and 62 is specifically designed to  
11 mate with the support notch 51 shown in Figure 3b. According to one embodiment of the  
12 present invention, the fixed support members 61 and 62 can be attached to the support  
13 plate 60 by cutting a hole in the support plate 60 to correspond to the shape and size of  
14 the fixed support members 61 and 62, passing the fixed support members 61 and 62  
15 through such hole, and then welding the fixed support members 61 and 62 in place. It  
16 will be appreciated by one of skill in the art that fixed support members 61 and 62 can be  
17 attached to support plate 60 by any suitable metal-to-metal connection method that is  
18 capable of handling the significant forces and stresses imposed on the support plate and  
19 fixed support members.

20 In addition, support plate 60 is specifically shaped to allow fixed support  
21 members 61 and 62 to be attached at locations on the support plate 60 such that they can  
22 engage support notches 51 of both mating lugs 46 and 47 to form the structural connector  
23 of the present invention. Specifically, as shown in Figure 4, fixed support member 62 is

1 attached to support plate 60 at a location that is lower than the attachment point for fixed  
2 support member 61 and further away from side box 11. Conversely, fixed support  
3 member 61 is attached to support plate 60 at a higher location than the attachment point  
4 for fixed support member 62 and closer to side box 11. As discussed in reference to  
5 Figures 5 and 5a below, this configuration allows fixed support members 61 and 62 to  
6 mate with the mating lugs on the mating lugs assembly to form the structural connector  
7 of the present invention.

8        Having described the individual elements of the structural connector of the  
9 present invention, the completed structural connector will be described with reference to  
10 Figures 5 and 5a. In Figure 5, the elements of the disclosed structural connector are  
11 shown vertically aligned such that the connection can be made up. Specifically, when the  
12 drilling rig is being assembled at the drilling site, the side boxes of the substructure will  
13 be placed on the ground and positioned in such a way that the unitized equipment floor  
14 can be lowered into place and connected to the side boxes. As shown in Figure 5, the  
15 mating lugs assembly 41 attached to the setback spreader assembly 22 is aligned above  
16 the support plate 60 attached to the side box 11 of the substructure. The mating lugs  
17 assembly 41 is aligned such that the support notches 51 in mating lugs 46 and 47 attached  
18 to mating lug plate 44 can be lowered into a mating position with fixed support members  
19 61 and 62 on one side of the support plate 60. In a similar fashion, the support notches  
20 51 of mating lugs 46 and 47 attached to mating lug plate 43 are mated with fixed support  
21 members 61 and 62 on the opposite side of the support plate 60. The tapered guide  
22 surfaces 55 and 56 of the support notches 51 act as a “guide” that guides the mating lugs  
23 46 and 47 into engagement with the fixed support members 61 and 62. The use of

1 tapered guide surfaces 55 and 56 further increases the efficiency with which the structural  
2 connector of the present invention can be made up.

3 When so connected, the mating lug plates 43 and 44 of the mating lugs assembly  
4 41 are on either side of the support plate 60 as shown in Figure 5a. In this configuration,  
5 the ends of fixed support members 61 and 62 extending outwardly on both sides of  
6 support plate 60 fit tightly within the corresponding notches 51 of mating lugs 46 and 47  
7 attached to mating plates 43 and 44. As such, the structural connector of the preferred  
8 embodiment of the present invention comprises a four point connection in which the ends  
9 of fixed support member 61 engage the two support notches 51 of the two mating lugs 46  
10 attached to mating lug plates 43 and 44, and the ends of fixed support member 62 engage  
11 the two support notches 51 of the two mating lugs 47 attached to mating lug plates 43 and  
12 44.

13 For larger drilling rigs, alternative embodiments of the present invention utilizing  
14 multiple support plates and additional mating lug plates can be used. For example, in one  
15 alternative embodiment, the structural connector may utilize two support plates – with  
16 each plate having two fixed support members extending therethrough – and a mating lugs  
17 assembly consisting of three mating plates. In such a configuration, the structural  
18 connector would comprise an eight point connection in the manner described above with  
19 reference to the preferred embodiment. In a like fashion, the number of support plates  
20 and number of mating plates used in another embodiment of the structural connector  
21 could be increased to three and four respectively to create an even stronger connection.  
22 One of skill in the art will recognize that numerous alternative embodiments of the  
23 present invention can be made by adding additional support plates and additional mating

1 lug plates to the structural connector to increase the load handling capability of the  
2 connection.

3 Similarly, one of skill in the art will recognize that numerous alternative  
4 embodiments of the present invention can be made by increasing the number of mating  
5 lugs attached to the mating lug plates and by increasing the number of corresponding  
6 fixed support members attached to the support plates. One of skill in the art will also  
7 recognize that numerous alternative embodiments of the present invention exist in which  
8 the number of mating lugs and fixed support members used in the structural connector  
9 can be increased at the same time the number of support plates and mating lug plates is  
10 increased. Further, one of skill in the art will recognize that, for connections handling  
11 smaller loads, the number of mating lugs attached to the mating lug plates and the  
12 number of corresponding fixed support members attached to the support plates can be  
13 reduced to one. Likewise, for smaller load applications, mating lugs assemblies having a  
14 single mating lug plate can be utilized.

15 In yet another alternative embodiment of the present invention, the location of the  
16 support plates and the location of the mating lugs assemblies can be reversed, i.e., the  
17 support plates can be attached to the unitized equipment floor (instead of the side boxes),  
18 and the mating lugs assemblies can be attached to the side boxes (instead of the unitized  
19 equipment floor). In such a configuration, the contoured tops of the fixed support  
20 members would face downward (in the direction of the ground) such that they could mate  
21 with upward facing mating lugs – with the opening of the support notch in the mating  
22 lugs facing upwardly.

1           The result of the mating of the support notches 51 of the mating lugs 46 and 47  
2   with the fixed support members 61 and 62 – as shown in Figure 5a – is a structural  
3   connector capable of handling the significant vertical forces imposed on the connection  
4   by the weight of the unitized equipment floor and the significant moment imposed on the  
5   connection by horizontal forces acting on the connection. The ability of the structural  
6   connector of the present invention to handle these significant forces and stresses is  
7   derived from the uniquely shaped support notches 51 (shown in detail in Figure 3b) and  
8   uniquely shaped fixed support members 61 and 62 (shown in detail in Figure 4b).  
9   Specifically, when the contoured tops 68 of the fixed support members 61 and 62 are  
10   engaged with the contoured top surface 54 of the support notch 51 of the mating lugs 46  
11   and 47, the vertical load caused by the weight of the unitized equipment floor is spread  
12   evenly over the entire contoured tops 68 such that the vertical load can be effectively  
13   carried by the fixed support members 61 and 62..

14           With respect to horizontal loads acting on the connection point, the structural  
15   connector of the present invention is capable of handling high horizontal loads. The  
16   horizontal load handling capability is attributable to the mating of the vertical, or  
17   substantially vertical, side walls 66 and 67 of the fixed support members 61 and 62 with  
18   the vertical, or substantially vertical, side walls 52 and 53 of the support notches 51 of the  
19   mating lugs 46 and 47. The use of vertical, or substantially vertical, side walls allows the  
20   horizontal loads imposed on the connection to be carried over a greater surface area.  
21   Specifically, unlike round, pin-type connectors, the side walls 66 and 67 of the fixed  
22   support members 61 and 62 are in contact with the side walls 52 and 53 of the support  
23   notches 51 along the entire length of the walls. Any horizontal forces acting on the

1 connection will be spread out over the entire surface of the walls and, thus, the stresses  
2 placed on the connection point by these horizontal forces is reduced. Further, if  
3 significant horizontal forces are expected, the length of the side walls 66 and 67 of the  
4 fixed support members 61 and 62 and the length of the side walls 52 and 53 of the  
5 support notches 51 can be increased to provide an even greater area to handle such forces.

6 While the apparatus, compositions and methods of this invention have been  
7 described in terms of preferred or illustrative embodiments, it will be apparent to those of  
8 skill in the art that variations may be applied to the process described herein without  
9 departing from the concept and scope of the invention. All such similar substitutes and  
10 modifications apparent to those skilled in the art are deemed to be within the scope and  
11 concept of the invention as it is set out in the following claims.
